Abstract

Objective: To determine whether Dong Quai, a Chinese herbal compound purported to be efficacious in treating menopausal vasomotor symptoms, has a therapeutic benefit in treating hot flashes among prostate cancer patients receiving androgen deprivation therapy.

Methods: A randomized double-blind placebo controlled trial was conducted involving 22 men receiving luteinizing hormone-releasing hormone agonist therapy for prostate cancer with bothersome hot flashes. After recording a baseline log of the frequency, duration and severity of daily hot flashes, patients were randomly assigned in a 1:1 ratio to receive daily placebo or Dong Quai for 3 months. Vasomotor and adverse events were recorded daily. Blood work including serum prostate-specific antigen (PSA), international normalized ratio of prothrombin time and partial thromboplastin time were recorded at baseline and at the termination of the study.

Results: Seventeen of the 22 patients enrolled completed the trial. Baseline vasomotor duration and severity were equivalent between the groups, however the number of hot flashes were significantly more in the Dong Quai group ($p = 0.02$). With respect to the change in number of hot flashes per day, there was a slight decrease in the mean number among the Dong Quai group which was insignificant. The absolute change and average percentage change in perceived hot flash severity was similar in both groups. There was no significant decrease in the duration of the hot flashes between the 2 groups. Disease progression based on either PSA increase or change in digital rectal exam was not observed in any patient.

Conclusion: In this small pilot study, there were no significant differences in the severity, frequency or duration of hot flashes among men receiving placebo or Dong Quai.

Résumé

Introduction : Nous avons cherché à déterminer si le Dong Quai (*Angelica sylvestris chinensis* ou angélique chinoise), une plante médicinale chinoise censée être efficace dans le traitement des symptômes vasomoteurs liés à la ménopause, procure des bien-

faits thérapeutiques aux patients atteints de cancer de la prostate présentant des bouffées vasomotrices pendant un traitement antian-drogène.

Méthodologie : On a mené un essai randomisé à double insu et contrôlé par placebo auprès de 22 hommes recevant un agoniste de l'hormone de libération de l'hormone lutéinisante (LHRH) pour le traitement d'un cancer de la prostate et présentant des bouffées vasomotrices inconfortables. Après avoir noté au départ la fréquence, la durée et la gravité des épisodes quotidiens de bouffées vasomotrices, on a réparti les patients aléatoirement selon un rapport de 1:1 pour recevoir chaque jour un placebo ou du Dong Quai pendant 3 mois. Les effets vasomoteurs et les réactions indésirables ont été notés chaque jour. Des analyses sanguines comprenant le taux sérique d'APS et le rapport international normalisé du temps de Quick et du temps de thromboplastine partielle ont été effectuées au départ et à la fin de l'étude.

Résultats : Dix-sept des 22 patients inscrits ont participé à l'étude jusqu'à la fin. La durée et la gravité des épisodes de bouffées vasomotrices étaient similaires dans les deux groupes au départ, mais le nombre d'épisodes de bouffées vasomotrices était significativement plus élevé dans le groupe recevant le Dong Quai ($p = 0,02$). En ce qui a trait à la variation dans le nombre d'épisodes quotidiens, une légère diminution a été notée dans le nombre moyen dans le groupe sous Dong Quai mais cette diminution s'est avérée non significative. La variation absolue et le pourcentage moyen de variation dans la gravité perçue des épisodes de bouffées vasomotrices étaient similaires dans les deux groupes. On n'a noté aucune diminution de la durée des épisodes dans les deux groupes. Aucune progression de la maladie, en fonction de changements dans les taux d'APS ou lors des touchers rectaux n'a été notée.

Conclusion : Dans cette petite étude pilote, aucune différence significative n'a été observée dans la gravité, la fréquence ou la durée des bouffées vasomotrices chez les hommes recevant un placebo ou du Dong Quai.

Introduction

Dong Quai, derived from the root of the Chinese herb *Angelica sinensis*, has been used for thousands of years in traditional Far Eastern medicine. Dong Quai has been named "female ginseng" because of its use for various health

conditions afflicting women including dysmenorrhea, pelvic pain, recovery from childbirth and menopausal symptoms, such as hot flashes.¹

Three randomized controlled trials have examined the use of Dong Quai for perimenopausal symptoms and menstrual migraine.²⁻⁴ Overall vasomotor episode reduction was noted in 20% to 35% of patients in several studies^{2,4} although another study failed to show any significant difference between Dong Quai and placebo.³ The study by Burke and colleagues did demonstrate a 56% reduction in menstrually associated migraine attacks.³

It is believed the physiologic mechanisms involved in the development of menopausal hot flashes in women and men prescribed androgen deprivation therapy (ADT) are analogous. Although the exact etiology of hot flashes is unknown, several theories have been proposed including increases in hypothalamic adrenergic levels, alterations in β -endorphins and a potential role of calcitonin gene-related peptides within the thermoregulatory centre in the hypothalamus.^{5,6}

It is well-established that the use of gonadotropin-releasing hormone agonist (GnRH) analogues are associated with hot flashes in more than 75% of patients.^{7,8} One study suggested that the frequency and severity of vasomotor symptoms were most prominent during the first year after castration.⁹ In contrary to postmenopausal hot flashes that usually disappear after 2 to 5 years, for men after orchidectomy or receiving continuous GnRH therapy, vasomotor symptoms usually persist. The duration of the symptoms may therefore be quite long, given that many more men are receiving these agents at an earlier stage in their disease.

The use of Dong Quai to manage hot flashes in men receiving ADT has not been previously reported to our knowledge and is the basis of this research.

Methods

We conducted a prospective randomized, double-blinded, placebo, controlled trial to assess the potential efficacy of Dong Quai in improving symptomatic hot flashes in men receiving ADT. The study was approved by The University of Western Ontario Health Sciences Research Ethics Board. Twenty-two patients receiving luteinizing hormone-releasing

hormone (LHRH) agonist monotherapy with either goserelin acetate, buserelin acetate or leuprolide were enrolled between January 2002 and July 2007. Indications for ADT in these patients included radiographically confirmed metastatic disease or biochemical progression following prior attempt(s) at definitive therapy. Men in this trial had been on ADT for an average of 17 months (range 2 to 51) before enrollment. The patients were randomized 1:1 to receive either Dong Quai or placebo. The herbal preparation (Swiss Herbal Remedies Ltd, Richmond Hill, Ontario) contained 500 mg of Dong Quai. The placebo preparation was an inert tablet manufactured by our hospital pharmacy to visibly resemble the Dong Quai tablet.

Exclusion criteria included: involvement in another clinical trial, pain requiring daily use of analgesics, life expectancy of less than 3 months, receiving anticoagulant therapy, history of bleeding disorder or known hypersensitivity to any constituent of DQ.

At each follow-up visit, participants completed a follow-up questionnaire where they noted any change in their prescribed or over-the-counter medications, change in their physical health and whether or not they had taken the study drug as instructed. Compliance was also assessed by counting the pills remaining in the returned study drug bottle.

The primary outcome measure assessed was the reduction in the incidence and severity of vasomotor episodes using an event log and symptom questionnaire at each of the 3 follow-up visits. The event log was used to document the severity of hot flashes, using a visual analog scale (VAS), and also to determine the date and time of hot flash events. The incidence of events was calculated by the number of events over time. The severity of an individual event was determined by using the average number of events recorded and the average VAS. The percent change in vasomotor occurrences and severity from baseline to each month of the study was calculated and compared between groups.

Both groups were subjected to an initial questionnaire to document the baseline hot flash symptom frequency and bother. Laboratory testing included determinations of prostate-specific antigen (PSA), partial thromboplastin time (PTT) and international normalized ratio of prothrombin time (INR). At 1 month, a run-in period of assessment was then conducted to record the frequency, severity and duration of all vasomotor events. The event severity was subjectively quantified by

Table 1. Patient demographics

	Placebo	Dong Quai	<i>p</i>
	n = 11	n = 11	n/a
Age	74.0 ± 8.15	72.5 ± 9.63	0.69
PSA	0.21 ± 0.38	0.30 ± 0.33	0.57
INR	1.02 ± 0.01	1.06 ± 0.01	0.19
PTT	30.6 ± 2.8	32.1 ± 2.5	0.29

PSA = prostate-specific antigen; INR = international normalized ratio of prothrombin time; PTT = partial thromboplastin time. Values represent mean ± standard deviations.

Table 2. Hot flashes at baseline

	Placebo	Dong Quai	<i>p</i>
	n = 11	n = 11	n/a
Episodes per day	3.42 ± 1.42	6.80 ± 4.33	0.02
Severity (0 - 10)	3.64 ± 1.37	3.76 ± 1.67	0.79
Duration in minutes	4.83 ± 3.38	3.33 ± 1.45	0.19

n/a = not applicable. Values represent mean ± standard deviations.

Fig. 1. Vasomotor events per day. Overall the Dong Quai group experienced more hot flashes than the Placebo group ($p = 0.02$). There was no change in the number of daily vasomotor events in either group ($p =$ not significant).

the patients using a 10-cm VAS. Patients kept daily records of these events which would be reviewed and collected each month by the research nurse. The study was done over a span of 4 months including the 1-month run-in, with all patients taking a daily pill each morning for 3 months. At the end of the study, repeat PSA, INR and PTT were tested.

The data were analyzed using Students' t-test and two-way analysis of variance, where appropriate, to compare the effects of treatment between the placebo and active treatment arms. Categorical data was analyzed with the Pearson chi-square test. Test significance was set at <0.05 .

Results

Eleven patients were included in the Dong Quai group and 11 in the placebo arm. The patient demographics were similar for both groups (Table 1). The patients' ages ranged from 72.5 to 74.0. The mean values at study entry for PSA, INR and PTT were 0.25, 1.04 and 31.4, respectively. Five patients, 3 from the placebo group and 2 patients from the Dong Quai group, withdrew from the study for reasons including gastrointestinal upset, headache, no perceived benefits, unrelated head injury and scheduling conflicts. No patient reported taking the active study drug from an over-the-counter preparation.

To understand the magnitude of the patients' symptoms, all patients completed questionnaires which revealed that 47.6% had trouble sleeping due to hot flashes. Only 4.8% had tried alternative treatments to resolve their hot flashes prior to their participation in this trial.

In the initial 1-month run-in, the placebo group had an average of 3.42 ± 1.42 vasomotor episodes per day while the Dong Quai group had 6.80 ± 4.33 episodes ($p = 0.02$). The severity of the episodes averaged 3.64 ± 1.37 in the placebo group versus 3.76 ± 1.67 in the Dong Quai group. The duration of the vasomotor symptoms lasted on average 4.83 ± 3.38 minutes in the placebo group and $3.33 \pm$

Fig. 2. Duration of vasomotor event. Hot flashes were of similar duration in both the placebo and Dong Quai groups ($p = 0.19$). There was no change in the duration of vasomotor events in either group ($p =$ not significant).

1.45 minutes in the Dong Quai group (Table 2).

The average number of vasomotor events experienced by the placebo group was 3.55 in the first month, 3.58 in the second and 2.84 in the third. The average number of vasomotor episodes for the Dong Quai group was 6.9 in the first month, 6.86 in second month and 6.43 in third month. Comparatively, there was no significant change in the daily number of vasomotor events in either group (Fig. 1).

The mean duration of hot flashes in the placebo group in the first month was 4.07 minutes, 4.1 minutes in the second and 3.52 in the third. Patients in the Dong Quai group experienced hot flashes for a mean time of 2.99 minutes in the first month, 3.28 in the second and 2.82 in the third. Neither group experienced a significant change in the average duration of their vasomotor events (Fig. 2).

The average hot flash severity subjectively recorded by patients in the placebo group in the first month was 3.66, in the second month was 3.66 and in the third month was 2.47. The patients in the Dong Quai group experienced 3.87 in severity of hot flashes in the first month, 3.27 in the second month and 3.71 in the third month. Vasomotor events were of similar severity in both groups ($p = 0.79$) (Fig. 3). The calculated percent change in perceived hot flash severity was similar in both groups ranging from 78 to 112% for the placebo group and 93 to 116% for the Dong Quai group (Fig. 3).

Coagulation studies were obtained for each patient in both groups before starting the study and at completion. Baseline

Table 3. Dong Quai ingredients

Volatile oils	ligustilide, n-butylidene phtalide, n-valerophenone-o-carboxylic acid
Furanocoumarins	psoralen, bergapten, archangelicin
Organic acids	ferulic acid, succinic acid, myristic acid
Miscellaneous	Vitamins A, B, E, polysaccharides including AR-4E-2, angelica immunostaining

Fig. 3. Percent change in perceived hot flash severity. Vasomotor events were of similar severity in both groups ($p = 0.79$). There was no change in the severity of hot flashes experienced by either group ($p =$ not significant).

and follow-up studies were normal in all patients. There were no clinical bleeding problems during the study interval.

The average baseline serum PSA for the placebo group was 0.21, however this increased to 1.11 at the end of the study due to one patient's progression to androgen refractory disease while in the study. In the Dong Quai group the mean baseline PSA was 0.3 and 0.39 at the end of the study (Table 1).

Discussion

Despite patients' increasing interest and willingness to try alternative therapies, there is a lack of scientific evidence to support many of these over-the-counter treatments. Most of these treatments are not subject to the same regulatory scrutiny as pharmaceuticals, as they do not require review by Food and Drug authorities before they are marketed.

Dong Quai, or *angelica sinensis*, is a herbal therapy that has been used extensively for the treatment of gynecological disorders for thousands of years in traditional Chinese, Korean and Japanese medicine. The therapeutic dose is uncertain however, with studies in the gynecologic literature using varying dosages from 75 mg to 1 g.²⁻⁴

The known constituents of Dong Quai are listed in Table 3.¹⁰ It had been believed that many of its effects were related to a phytoestrogenic effect, however this assumption is now questioned.^{1,11} Animal studies have failed to identify any estrogenic activity.^{1,12}

Adverse effects related to the use of Dong Quai appear to be very rare. Diarrhea and photosensitivity have been reported.¹¹ As one component of Dong Quai includes furanocoumarins, the potential exists for potentiation of bleeding complications for those patients receiving concomitant anticoagulant therapy.¹¹⁻¹³ We did not identify any bleeding complications in our series.

Hot flashes induced by ADT are typically described as a sudden onset of flushing sensation involving the face and neck. Huggins, Stevens and Hodges in their seminal work on the effects of castration for men with advanced prostate cancer described hot flashes as "profuse perspiration, often occurring at night, forcing the patient to throw off the bed covers".¹⁴ Prostate cancer patients receiving ADT commonly experience similar vasomotor symptoms as menopausal women. Although most men do not require treatment, a prospective trial found that 11.3% of patients found hot flashes distressing enough to negatively affect their quality of life.⁹

Various pharmaceuticals have been used for those men requiring therapy with varying degrees of success. Cyproterone acetate, medroxyprogesterone acetate and clonidine have been reported to be helpful in some patients, although not without the cost of inducing their own side effects.^{15,16} Estrogens have also been used, however the cardiovascular side effects have limited their application.^{17,18} The antidepressant venlafaxine also demonstrated efficacy in reducing hot flashes, but in a small non-placebo controlled series it was associated with a 10% dropout rate due to nausea.¹⁹ The most successful results have been reported with the progestational agent megestrol acetate. In a placebo-controlled crossover trial, hot flash frequency was diminished by 85%.²⁰ Two prior studies identified a 20-30% decrease in the frequency of hot flashes during a 4-week placebo run-in phase.^{20,21}

Limitations of this study include the small pilot sample size which might miss a mild potential benefit, and the individual subjectiveness of recording hot flash severity. As the therapeutic dose of Dong Quai is unknown, it is possible that a different outcome may have been observed at a higher dosage or with a longer duration of treatment.

Conclusion

Hormonally treated prostate cancer patients taking Dong Quai in this pilot study showed no change in the duration or severity of their vasomotor events. Dong Quai was well-tolerated and safe, but its benefits remain unproven for this population of patients.
